## STUDIES RELATED TO WILDERNESS

### Bureau of Land Management Wilderness Study Areas

The Federal Land Policy and Management Act (Public Law 94-579, October 21, 1976) requires the U.S. Geological Survey and the U.S. Bureau of Mines to conduct mineral surveys on certain areas to determine their mineral resource potential. Results must be made available to the public and be submitted to the President and the Congress. This report presents the results of a mineral survey of the Crossman Peak Wilderness Study Area (5-7B), Mohave County, Arizona.

### INTRODUCTION

During 1979-1982, the U.S. Geological Survey and the U.S. Bureau of Mines conducted field investigations to evaluate the mineral resources of the Crossman Peak Wilderness Study Area (5-7B), Mohave County, Arizona. Field studies included geologic mapping, geochemical sampling, geophysical surveys, and a survey of known mines, prospects, and mineralized areas. This report complements the mineral resource appraisal of the Crossman Peak Wilderness Study Area (Light and others, 1983) and presents the analytical results for samples from mineral occurrences in and around the study area. These samples were collected by the U.S. Bureau of Mines and analyzed by the U.S. Geological Survey.

The Crossman Peak Wilderness Study Area comprises approximately 38,000 acres in western Mohave County, Arizona, three miles east of Lake Havasu City, Arizona, and 45 miles southwest of Kingman, Arizona (fig. 1). The area is accessible from the north and west by numerous jeep trails that intersect either Interstate 40, State Highway 95, or some residential streets of Lake Havasu City. From the south, southeast, and northeast access to the area is by jeep trails that intersect the unimproved Dutch Flat Road, which skirts the south flank of the mountains.

Rocks in the wilderness study area are dominantly Proterozoic granite gneisses and amphibolite intruded by Proterozoic and Tertiary igneous dikes (Howard, Goodge, and John, 1982; John and Howard, 1982). A small granitic stock of Cretaceous(?) age crops out in the northern portion of the study area. Numerous Tertiary mafic to silicic dikes have intruded the Proterozoic rocks throughout the study area. A dense swarm of northwest trending dikes intrude much of the western and southern portions of the area (Nakata, 1982). Along the southern and southwestern borders of the study area, the Proterozoic rocks are unconformably overlain by Tertiary volcanic and sedimentary units including flows, breccia, and tuff of silicic to basaltic composition, fanglomerate, conglomerate, sandstone, and claystone (Pike and Hansen, 1982).

The Crossman Peak Wilderness Study Area contains numerous occurrences of gold, silver, tungsten, lead, and zinc in northeast to northwest trending veins and faults which cut the Proterozoic gneisses. These deposits have been prospected and mined intermittently over the past 120 years. Lode base and precious metal concentrations have been mined or prospected at 39 separate localities in and around the Crossman Peak Wilderness Study Area (Light and others, 1983). These sites range from patented lode mining claims with several thousand feet of workings to areas with numerous shallow pits and

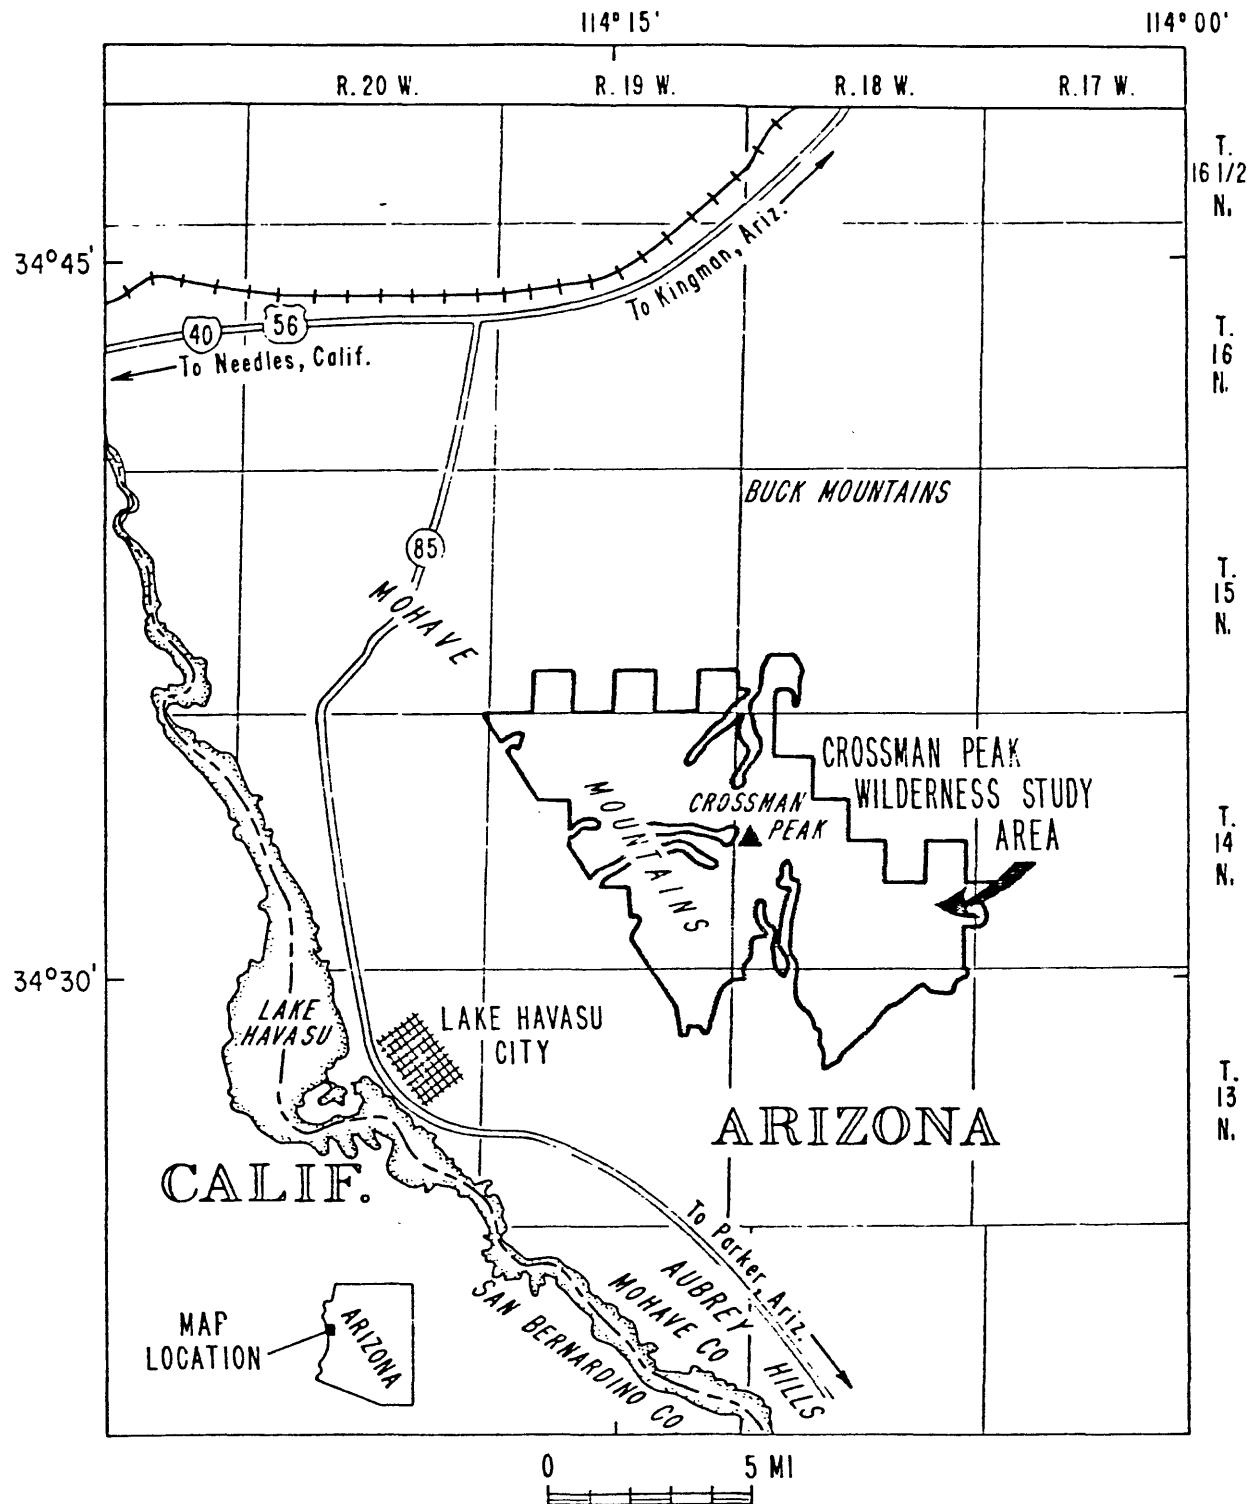

Figure 1.--Location of Crossman Peak Wilderness Study Area (5-7B),  
Mohave County, Arizona

short adits. Although only limited data are available on the tonnage and grade of ore produced, sixteen of these areas were reported to have produced some ore (Light and McDonnell, 1983) and several other areas probably produced some high-grade ore.

The overlapping zoned distribution of base and precious metals in the Crossman Peak Wilderness Study Area has been interpreted to represent the expression of a large hydrothermal system that may be related to a porphyry at depth (Light, Marsh, and Raines, 1982).

The region encompassing the study area includes the topographically rugged center and flanking foothills of the Mohave Mountains. Elevations range from approximately 1800 feet near Standard Wash at the southern edge of the study area to 5100 feet at the top of Crossman Peak.

## METHODS OF STUDY

### Sample Collection

Field investigations by U.S. Bureau of Mines personnel were focused on known mines, prospect workings, and mineral occurrences. Locations of mining claims were examined, and were sampled where workings or mineralization was encountered. Surface and underground workings were examined and were mapped and sampled where accessible. Detailed sample descriptions and maps of surface and underground workings were compiled by Light and McDonnell (1983). A total of 970 rock samples were collected including chip, select, and outcrop samples. Where possible, mineralized structures were sampled at approximately 20-foot intervals. Chip samples were cut across a vein or mineralized structure as a representative cross-section. Select samples were intentionally chosen to illustrate high-grade mineralization.

### Sample Preparation and Analysis

Rock samples were crushed and then pulverized with ceramic plates to at least minus-100-mesh (0.15 mm).

All samples were analyzed for 31 elements using a semiquantitative, direct-current arc emission spectrographic method (Grimes and Marranzino, 1968). The elements analyzed and their lower limits of determination are listed in Table 1. Spectrographic results were obtained by visual comparison of spectra derived from the sample against spectra obtained from standards made from pure oxides and carbonates. Standard concentrations are geometrically spaced over any given order of magnitude of concentration as follows: 100, 50, 20, 10, and so forth. Samples whose concentrations are estimated to fall between those values are assigned values of 70, 30, 15, and so forth. The precision of the analytical method is approximately plus or minus one reporting unit at the 83 percent confidence level and plus or minus two reporting units at the 96 percent confidence level (Motooka and Grimes, 1976). Values determined for the major elements (iron, magnesium, calcium, and titanium) are given in weight percent; all others are given in parts per million (micrograms/gram)

TABLE 1.--Limits of determination for the spectrographic analysis of rocks and stream sediments, based on a 10-mg sample

[The spectrographic limits of determination for heavy-mineral-concentrate samples are two reporting units higher than the limits given for rocks and stream sediments]

Elements	Lower determination limit	Upper determination limit
Percent		
Iron (Fe)	0.05	20
Magnesium (Mg)	.02	10
Calcium (Ca)	.05	20
Titanium (Ti)	.002	1
Parts per million		
Manganese (Mn)	10	5,000
Silver (Ag)	0.5	5,000
Arsenic (As)	200	10,000
Gold (Au)	10	500
Boron (B)	10	2,000
Barium (Ba)	20	5,000
Beryllium (Be)	1	1,000
Bismuth (Bi)	10	1,000
Cadmium (Cd)	20	500
Cobalt (Co)	5	2,000
Chromium (Cr)	10	5,000
Copper (Cu)	5	20,000
Lanthanum (La)	20	1,000
Molybdenum (Mo)	5	2,000
Niobium (Nb)	20	2,000
Nickel (Ni)	5	5,000
Lead (Pb)	10	20,000
Antimony (Sb)	100	10,000
Scandium (Sc)	5	100
Tin (Sn)	10	1,000
Strontium (Sr)	100	5,000
Vanadium (V)	10	10,000
Tungsten (W)	50	10,000
Yttrium (Y)	10	2,000
Zinc (Zn)	200	10,000
Zirconium (Zr)	10	1,000
Thorium (Th)	100	2,000

## ROCK ANALYSIS STORAGE SYSTEM

Upon completion of all analytical work, the analytical results were entered into a U.S. Geological Survey computer-based file called RASS (Rock Analysis Storage System). This RASS file contains both descriptive geological information and analytical data. Any or all of this information may be retrieved and converted to a binary form (STATPAC) for computerized statistical analysis or publication (VanTrump and Miesch, 1976).

## DESCRIPTION OF DATA TABLES

Table 2 lists the analyses for the rock samples from mineralized localities. The data are arranged so that column 1 contains the USGS-assigned sample numbers. These numbers (minus the "CP" prefix) correspond to the numbers shown on Plate 1. Fluorine was determined by a specific ion electrode method (Hopkins, 1977). All other elements were determined by emission spectrographic analyses. A letter "N" in the tables indicates that a given element was looked for but not detected at the lower limit of determination for that element (table 1). If an element was observed but was below the lowest reporting value, then a "less than" symbol (<) was entered in the tables in front of the lower limit of determination. If an element was observed but was above the highest reporting value, then a "greater than" symbol (>) was entered in the tables in front of the upper limit of determination. If an element was not looked for in a sample, then two dashes (--) are entered in place of an analytical value. Because of the formatting used in the computer program that produced Table 2, some of the elements listed in this table (Fe, Mg, Ca, Ti, and Ag) carry one or more nonsignificant digits to the right of the significant digits. The analysts did not determine these elements to the accuracy suggested by the extra zeroes.
